AUTHOR: Vítek, Vojtěch

TITLE: Some hydrodynamic aspects of high-level cyclogenesis

PERIODICAL: Studia geoph. et geod., no. 1, 1960, 59-68

TEXT: In this paper the author tries to give a very elementary hydrodynamical interpretation of the origin of a field of motion during cutoff. The actual atmosphere was simplified as far as was physically possible. This interpretation is based on the assumption that a necessary initial condition for the whole process is zero absolute vorticity on the southern boundary of the jet stream which, for the sake of simplicity, will be regarded as a straight zonal flow. The possibility of the occurrence of negative absolute vorticity is not taken into consideration. This paper partly answers the question, whether the main features of the processes during high-level cyclogenesis can be represented by means of a simple barotropic model. The results of the paper are: a differential equation describing the field of motion during high-level cyclogenesis can be obtained from the equation of motion of horizontal friction-less flow; the physico-mathematical solution of this problem indicates similarity to a

Some hydrodynamic aspects ...

certain hydrodynamic problem; the production of closed cyclonic circulation around a stratospheric drop "submerged" into a jet stream can be described by means of the ageostrophic barotropic model. The author expresses his thanks to Doctor Z. Gregor for valuable discussion, and to Doctor J. Podzimek for helpful criticism of the manuscript. Reviewer: J. Podzimek. There are 7 references: 1 Soviet-bloc and 6 non-Soviet-bloc. The reference to the most recent English-language publication reads as follows: F. Defant, H. AUTHOR: Vítek, Vojtěch

TITLE: On the problem of cold air production beneath thunderstorm clouds

PERIODICAL: Studia Geophysica et Geodaetica, no. 2, 1961, 164-170

TEXT: This paper deals with the theoretical aspects of the law which governs the outflow of cold air from the precipitation area beneath the Cb and parameters which determine the motion of the pseudocold front. The results obtained have an orientational character mainly, and depict the conditions beneath small, isolated thunderstorm cells in cases where the vertical wind shear is not pronounced. The results also confirm the empirical fact that the production of cold air beneath a Cb is the more intensive, the stronger is the preceding updraft in the Cb. This dependence is formulated quantitatively by determining the relation between the updraft velocities and the acceleration of the pseudo-front. The time of existance of the pseudo-cold front is also determined theoretically and a relation derived for the pressure rise connected with its arrival.

Card 1/2

On the problem...

The proposed model of the process should quantitatively explain the main features of the outflow of cold air, but not the details. In a more detailed elaboration some of the physico-chemical processes influencing the precipitation mechanism in a Cb would have to be taken into consideration and a more detailed study made of the hydrodynamic and thermodynamic side of the process. The author continues by treating the problem mathematically. The author thanks Dr. J. Podzimek for helpful criticism. There are 3 references: 1 Soviet-bloc and 2 non-Soviet-bloc. TITLE: A proposal of a method for objective forecast of the 300-mb level

PERIODICAL: Studia geophysica et geodaetica, 6, no. 2, 1962, 202-205

TEXT: A prognostic equation for forecasting the changes in the 300-mb isobaric level is developed. Introducing specified simplifying conditions, this equation is reduced to a very simple expression which lends itself readily to graphical integration. A statistical evaluation of some forecasts made according to this method indicates that the calculated correlation coefficients are approximately comparable to those of the 500-mb level, but the mean square errors are larger. A final conclusion as to the adequacy of the method cannot be made at the present time due to the small number of tests made so far. The tests are being continued to determine to what extent the found errors were due to a random preselection of weather situations. The theory of this method was originally presented at a seminar of the Hydrometeorological Institute held on January 13, 1960

TITLE: Expansion of Oscillatory Regions of Decimeter-Band Magnetrons. A Short Report (O rasshirenii kolebatel'nykh zon magnetronov detsimetrovogo diapazona. Kratkoye soobshcheniye)

PERIODICAL: Radiotekhnika i Elektronika, 1957, Vol 2, Nr 1, pp 120-121 (USSR)

ABSTRACT: Split-anode magnetrons with a small number of segments and Lecher-type resonant lines may be used as easily tunable higher-frequency oscillators of the decimeter band. Results of experiments with 4- and 6-segment magnetrons having a thin cathode and a Lecher frame functioning in a nonresonant region are reported. The anode radius of the magnetron was 0.5 cm, cathode radius, 0.015 cm; straps were used to secure π-mode oscillations. At an anode voltage within 1,000 to 3,000 volts and at a higher-than-critical magnetic field, an aperiodic load can bring about an appreciable expansion of the oscillatory region and, consequently, a possibility of obtaining a higher frequency deviation corresponding to a given anode-voltage change. The frequency deviation may reach $\pm$ 10%. The maximum width of the oscillatory region was obtained with small anode currents.

TITLE: Frequency modulation of travelling wave laboratory magnetrons of the decimetric wave-range

PERIODICAL: Referativnyy zhurnal. Avtomatika i radioelektronika, no. 6, 1962, 14, abstract 6Zh102 (Nauchn. yezhegodnik. Saratovsk. un-t. Fiz. fak. i N.-i. in-t mekhan. i fiz. 1955, Saratov, 1960, 111-116)

TEXT: The dependence of magnetron frequency on anode voltage is determined on the basis of expressions for the HF conductivity, for thin cathode magnetrons having a small number of segments. It is shown that it is possible to obtain frequency modulation with sufficiently large frequency deviation in decimeter range magnetrons. The results of theoretical calculations are in satisfactory agreement with experiment. [Abstracter's note: Complete translation.]

TITLE: On the Problem of Widening the Oscillation Zones of Magnetrons Consisting of a Few Segments (K voprozu o rasshirenii zon kolebaniy malosegmentnykh magnetronov)

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy, Radiofizika, 1958, Nr 4, pp 105-110 (USSR)

ABSTRACT: A number of experiments were carried out on few-segment magnetrons (Ref 4 and 5) which operated with a non-resonant anode load in strong magnetic fields (about two times higher than the critical field). The experiments showed that it was possible to obtain frequency modulation over a range of about ± 10% of the centre frequency. It was found that the frequency characteristics are represented by the following expression:

$$\lambda(\text{cm}) = \frac{942\, r_a^2 H}{pU_a} \qquad (1)$$

06496

SOV/141-58-4-12/26

On the Problem of Widening the Oscillation Zones of Magnetrons Consisting of a Few Segments

In the present work the attempt was made to employ a two-conductor line as a wide-band anode load. The magnetrons used in the experiments had the anode radius $r_a = 0.5$ cm, $l_a = 1.5$ cm (the length of the anode), $r_k = 0.015$ cm (radius of the cathode) and the number of segments N was 2, 4 or 6; the segments were strapped in pairs in order to obtain the π-mode of oscillations. During the experiments, the supply voltages were carefully stabilized; in particular, the heaters were supplied from accumulators while the anode voltage was provided by a low-ripple stabilized supply. The electromagnet was supplied from a constant current generator operating at 120V. The experimental results are shown in Fig 3, 4, 5, 6 and 7. Fig 3 illustrates the frequency dependence on the anode voltage for a magnetic field H = 1200 Oe for various heater currents J_H; the length of the anode line was 5 cm and the tube employed two segments. Fig 4 represents the frequency characteristic of a two-segment magnetron,

Card 2/4

On the Problem of Widening the Oscillation Zones of Magnetrons Consisting of a Few Segments

when the anode circuit was in the form of short-circuited Lecher wires whose length was varied from 4 to 20 cm. Fig 5 represents the frequency dependence of a two-segment magnetron on the length of the anode line. Similar investigations were done on a six-segment magnetron and the results are shown in Fig 6 for various lengths of the anode line. Fig 7 illustrates the frequency-voltage dependence of a six-segment magnetron in which an anode circuit was in the form of an open-circuit Lecher wire. From the above experimental data it is concluded that, in the magnetrons consisting of a few segments, it is possible to obtain a voltage dependent frequency change of the order of $\pm$ 10%; the oscillations produced are of the π-type mode and obey the Postumus equation. The author expresses his

Abstract : The article reports on different conferences of the Oceanographic Commission of the Geographic Society in Leningrad devoted to the new research on the Sun and its functions, and to the annual issue on hydrometeorological observations of the sea. Another conference was held in Minsk where hydrological research problems were considered. A conference held in Chernovitsy discussed the problems of short-range forecasting. A conference of the Sverdlovsk Scientific Research Geophysical Observatory reported their findings on electricity in thunderclouds and on diurnal temperature changes.

TITLE: Characteristics of Long-Range Variations in the Atmospheric Circulation of Western Europe and Western Siberia Related to the 11-year Solar Cycle (O nekotorykh osobennostyakh mnogoletnikh kolebaniy atmosfernoy tsirkulyatsii v zapadnoy Yevrope i zapadnoy Sibiri, svyazannykh s odinnadtsatiletnim solnechnym tsiklom)

PERIODICAL: Trudy Glavnoy geofizicheskoy observatorii, 1956, Nr 65(127), pp. 5-7 (USSR)

ABSTRACT: The article discusses the difficulties of long-range prognostication. In order to facilitate the solution of such problems, only one element is selected--the variations of atmospheric circulation related to the 11-year solar cycle, as expressed by the recurring monthly anomaly of the baric- circulation cycle. There are 1 figure and 3 references, all USSR.

Voprosy sinoptichesko klimatologii. (Problems in Synoptic Climatology) Leningrad, Gidrometeoizdat, 1959. 105 p. (Series: Its: Trudy, vyp. 87) 1,100 copies printed.

Sponsoring Agency: Glavnoye upravleniye gidrometeorologicheskoy sluzhby pri Sovete Ministrov SSSR.

Ed. (Title page): T.V. Pokrovskaya, Candidate of Geographical Sciences; Ed. (Inside book): T.V. Ushakova; Tech. Ed.: A. N. Sergeyev.

PURPOSE: This issue of the Observatory's Transactions is intended for meteorologists and climatologists.

COVERAGE: The authors are primarily concerned with the possibility of using various monthly characteristics of atmospheric circulation in forecasting monthly air temperature anomalies. One of the articles discusses the inertia of the temperature and its utilization in forecasting. Other articles are concerned with the effects of solar activity on atmospheric circulation. The last article is devoted to the probability of cyclical regional distribution of mean negative diurnal temperatures, offering also a synoptic and climatological analysis of the results obtained. References accompany each article.

AUTHOR: Vitel's, L. A.

TITLE: The anomaly of cyclic processes of solar activity and the tendency of present climate variations

SOURCE: Leningrad. Glavnaya geofizicheskaya observatoriya. Trudy. no. 133, 1962, Voprosy obshchey i sinopticheskoy klimatologii, 35 - 54

TEXT: A method of determining annual anomalies of solar activity considering an 11-year cyclicity is suggested, Wolf's number standards for each year of the 11-year cycle are determined, deviations from these standards in absolute and relative units for all years beginning with 1749 are computed, a high degree of uniformity of anomalies within each 11-year cycle is revealed, a curve of the long-time course of Wolf's number anomalies corroborating the existence of a cycle in the order of 80 - 90 years is plotted. As a result it proved possible to divide the whole period considered into epochs characterized by clear-cut anomalies of solar activity and to state considerations as to the future long-time trend of solar activity and climate variations connected with it. As the

Card 1/4

The anomaly of cyclic processes of...

author points out, the final purpose of numerous studies of long-time changes of various climatic and hydrological characteristics is to reveal such laws of present climate variations and the factors conditioning them, which will enable one to forecast with a sufficient degree of reliability the main characteristics of future climate changes. Also the new problems connected with the large-scale projects of climate control make climate forecasting one of the most essential tasks of meteorology. Neither a mere extrapolation of long-time curves of this or that element, nor the forecasts based on different periods, as long as the physical nature of this periodicity is unclear, can serve as a basis for forecasts. At present the only serious basis for climate-variation forecasts are heliogeophysical connections, i.e., laws connecting climate variations through the mechanism of overall atmosphere circulation with the solar activity. The relative numbers of sun-spots W (Wolf's numbers) are the most widely used indices of solar activity, whereby the deviations of W from the standard computed for a sufficiently long period (200 - 250 years) are taken for anomalies of solar activity. In the reviewed study ΔW is computed in deviations from the W standard computed for each individual year of the 11-year cycle. The work is rendered complicated by the fact that the duration of solar cycles fluctuates within broad

The anomaly of cyclic processes of...

limits. So, since 1749 at an 11.1-year average cycle duration, there were very short cycles (9 years) and very long cycles (13.6 years). Following the course of ΔW and $\frac{W}{W_{av}}$ (W_{av} = the average W value in the year of maximum) the author discovers besides 11-year cycles longer epochs of similar type (the same sign of ΔW) anomalies of solar activity. These epochs are distinctly separated from each other and their boundaries in a predominant majority of cases coincide with minimum years of 11-year cycles, thus revealing the physically self-contained character of 11-year cycles. For the purpose of solar-activity forecasts the number of anomaly sign changes is important, which is determined by the equation $a = 2pqn$, where p is the probability of positive anomaly, q is the probability of negative anomaly, and n is the number of members of the series. The probable error of a is $P_a = 1.348\sqrt{pq(n-1)(1-3pq)}$. Based on his data and on the relevant literature, the author draws a conclusion on the existance of secular or 80-year cycles of solar activity which, together with the epochs established by the author (semicycles), provide a foundation for forecasts. First of all a considerable weakening of general atmosphere circulation may be expected. Especially noticeable will be the decrease of intensity of cyclone activity in high latitudes.

Card 3/4

The anomaly of cyclic processes of...

The planetary upper frontal zone in high northern latitudes will occupy a more southern position. Cyclones passing before through Soviet northern seas will move along more southern trajectories, through the northern part of the European USSR including the central regions. The processes of zonal transfer will be observed more frequently and the frequency of eastern processes will decrease. Also will decrease the change frequency of circulation forms, and the average duration of periods of one-type circulation will increase. The continental character of the climate of the European USSR and western Siberia will increase. Winter temperatures will drop, arctic intrusions will be more vigorous, and the icyness of the arctic seas will increase. The natural discharge in the Volga valley will increase. The Caspian sea level (without taking into account artificial measure and water intake from the Volga) will rise. There are 4 figures and 5 tables.

AUTHOR: Vitel's, L.A.

TITLE: The effect of solar activity on degree of distinctness of intra-atmospheric prognostic correlations

PERIODICAL: Referativnyy zhurnal. Astronomiya i Geodeziya, no. 1, 1962, 62, abstract 1A468 ("Solnechnyye dannyye", 1960 (1961), no. 10, 70 - 73)

TEXT: It is known that there are asynchronous correlations in the troposphere. Thus, e.g., some types of circulation anomalies may be reflected, after a few months, in one or another macrosynoptic characteristic. One of the examples of such correlations is dependence of precipitates in October in the north-west of the European part of the USSR on development of anticyclonicity in the South-Western Siberia during 12 - 13 months preceding October. The author raises the question, whether the distinctness of asynchronous correlation may be a function of the phase of 11-year solar cycle. In order to check the hypothesis advanced, L.A. Vitel's divided six 11-year cycles into 3 phases: the year of minimum and the beginning of the ascending branch (up to +2nd year from the minimum inclusive); the end of the ascending branch, the year of maximum and 2 years after

Card 1/2

33623
S/035/62/000/001/014/038
A001/A101

The effect of solar activity ...

the maximum; the descending branch beginning from the +3rd year after the maximum. Prognostic correlations proved to be of different distinctness at different phases of the 11-year cycle. In the first phase the correlation is the least pronounced, a somewhat more pronounced it is in the second phase, and the most distinct in the third phase of the 11-year cycle, when the accuracy of forecasting amounts to 100%. The author explains this correlation of intraatmospheric regularities with the phase of solar activity cycle by Sperer's law: during the third phase of the 11-year cycle the Earth is in the most favorable position in the sense of being hitted by solar corpuscles, since in this time active solar formations are distributed at the lowest heliographic latitudes. Solar effects, according to P.P. Predtechenskiy and the author, lead to ordering of atmospheric circulation and to more pronounced distinctness of intraatmospheric correlations.

AUTHOR: Vitel's, L.A.

TITLE: Problems of improving and practically using the synoptic-climatologic ethod of long-range hydrometeorological forecasts

SOURCE: Leningrad. Glavnaya geofizicheskaya observatoriya. Trudy, no. 111, 1961. Voprosy obshchey i sinopticheskoy klimatologii, pp 136-152.

TEXT: This article deals with the practical application and improvement of the synoptic-climatologic method of long-range hydrometeorological forecasting, developed by the author at the Glavnaya geofizicheskaya observatoriya im. A.I. Voyeykova (Main Geophysical Observatory im. A.I. Voyeykov). The method is based on the presence of atmospheric processes developing regularly during seasonal, yearly or longer periods. Processes leading to large monotypic anomalies of meteorological conditions or to hydrological elements depending on atmospheric conditions have similar characteristics. The comprehensive use of meteorologic-synoptic and

Card 1/3

Problems of improving and practically...

hydrologic characteristics, as shown by A.B. Kryzhanovskaya of the Institut gidrologii i gidrotekh iki AN USSR (Institute of Hydrology and Hydraulic Engineering of the AS UkrSSR), M.I. Gurevich, V.V. Lebedeva and T.N. Makarevich, essentially improves prognostic relationships. The author stresses that his prognostic point is not the result of "the artificial selection of many variables outwardly reducible to one independent variable" as stated by N.A. Belinskiy and G.P. Kalinin (Ref. 1: Ob odnom metode prognozov gidrometeorologicheskikh elementov ["On one method of forecasting hydrometeorologic elements"]. Meteorol. i gidrol., no. 10, 1958), but a characteristic which permits quantitively evaluating the similarity between current and typical processes. The method, therefore, appears as a variation of the analogue method rather than a multiple correlation method. The numerical data of a synoptic catalogue help characterize baric and circulation conditions. Groups of events, i.e. days, months, etc., with genetically monotypic phenomena or anomalies of hydrometeorologic conditions should be selected. Sub-grouping, if required, should be considered. If the small number of events do not permit subgrouping, events whose basic characteristics differ from those of the group should be eliminated. After monotypic events have been selected

Card 2/3

Problems of improving and practically...

and groups with contrasting anomalies established, past development of processes should be studied in order to find phases showing the difference between processes leading to positive and negative anomalies of the element to be predicted. This development should be studied on qualitative and quantitative bases. On the basis of maps of baric and circulation anomalies, the months evidently contrasting in the general trend of the processes are selected. For these months, regions, which most distinctly show how these groups are contrasted, should be established. The quantitative characteristic - the frequency of the positive baric and circulation anomaly - will greatly differ for each region, and the signs of the anomaly in the corresponding region-months will appear as prognostic features. The criteria for selecting these features are discussed. M.S. Kaganer, B.P. Mul'tanovskiy and L.P. Vishnevskaya are mentioned. There are 3 figures, 2 tables and 6 Soviet references.

Card 3/3

Experimental analysis of prognostical...

atmospheric anomalies), it was found that the pronounced development of a West-Siberian anticyclone in the presence of cyclonic activity in northern Europe intensifies this activity and increases the probability of heavy precipitations, because such weather conditions favor the transfer of warm and moist air masses from the south to the European part of the USSR. An analysis of the baric and circulation conditions of the preceding months further revealed that the intense development of the West-Siberian anticyclone, which is characteristic for wet October months in the north-west European part of the USSR, is typical for nearly all months of the annual period preceding the wet October months. Under the condition that forecasts were made 1-3 months prior to the occurrence of a specific phenomenon, the reliability of the forecast of the sign of anomaly of the October precipitations was established at 64-66%. The reliability of the forecast can be increased by taking solar activity into account. It was established that the closeness of the studied prognostic relationship is subject to fluctuations depending on the phase of an 11 year solar

Card 2/3

Experimental analysis of prognostical...

cycle. It is at its maximum (above 90%) at the end of the cycle and abruptly decreases between the end of one cycle and the beginning of another one. The author considers that this solar effect is not so much due to the cyclic formation of sun spots as to the heliographic latitude of the spots and other active centers changing in accordance with the Spoerer law. In connection with heliogeophysical problems, the following scientists are mentioned: V.Yu.Vize, P.P. Predtechenskiy, E.R. Mustel', M.S. Eygenson, M.N. Gnevyshev, and R.S. Gnevysheva. There are 6 figures, 6 tables, and 12 Soviet references.

Card 3/3

AUTHOR: Vitel's, L. A.

TITLE: The effect of solar activity on the degree of closeness of intra-atmospheric prognostic connections

PERIODICAL: Referativnyy zhurnal, Geofizika, no. 8, 1961, 47-48, abstract 8B322 ("Solnechnyy dannyye", 1960, (1961), no. 10, 70-73)

TEXT: The Sun-troposphere problem is presently being studied in two trends: 1) investigating the connection between the solar activity, expressed by Wolf numbers or other indices, and the one or another meteorological characteristic; 2) investigating the intramass asynchronous connections of prognostic significance and studying the changes in the closeness of these connections depending on variations of the solar activity. The author chose the latter method and studied the effect of solar activity on the closeness of prognostic connections, by taking into account the phases of an 11-year cycle, which differ by the mean latitude of the spotforming zone. The author analyzes the connection between October precipitates at the north-west of the European territory of the USSR (ETS) and the conditions of atmospheric circulations of the four preceding seasons.

Card 1/2

S/169/61/000/008/029/053
A006/A101

The effect of solar activity ...

As a result the prognostic symptom was obtained that before rainy Octobers, positive anomalies of circulations prevail during 12 - 13 months in South-West Siberia. This symptom is justified to 64 - 66% at 1 - 3 months in advance. The problem was set up to reveal the conditions for the most certain justification of the prognostic symptom. The 11-year cycle of solar activity was divided into 3 phases: 1) the year of the minimum and the commencement of the ascending branch (to the +2nd year from the nimimum), 2) the end of the ascending branch, the year of maximum and two years following the maximum; 3) the last years of the descending branch of the cycle. It was found that the percentage of justifying the prognostic symptom was least in the first phase and highest in the third phase. This result is explained by the effect of variability in the mean latitude of spot formation and conditions of arrival on the Earth of geoactive radiation. At the beginning of the 11-year cycle new spots appear in the highest latitudes of the spot formation zone; therefore the conditions of solar activity are least favorable. By the third phase, the latitude decreases and the effect of geoactive radiation on atmospheric processes increases. As a conclusion the author mentions the significant part of the degree of stability of the solar rythm, connected with the 27-day cycle, on the atmosphere.

TITLE: The Possible Cause of the Change in the Relationship Between the Sun and the Terrestrial Atmosphere

PERIODICAL: Meteorologiya i gidrologiya, 1960, No. 7, pp. 9 - 13

TEXT: Papers by Ye. Ye. Fedorov, V. Yu. Vize, et al. show that the relationship between the Sun and the terrestrial atmosphere has no universal and invariable character. In the present paper, the author endeavors to clarify the relationship between the Sun and the terrestrial atmosphere by introducing a hypothesis. He refers to a model of this relationship suggested by L. R. Rakipova (Refs. 5 and 6), and gives a brief description of the development of cyclones and anticyclones. The heating of the atmosphere by solar corpuscles is investigated, and it is noted that the relationship between solar activity and the intensity of cyclones and anticyclones cannot always be expressed very clearly, even if different assumptions are made for the energy of corpuscular radiation. On the strength of the latest measurements, the author states
